(57) **ABSTRACT**

A phase modulation (PM) noise reducer includes: an amplitude modulation (AM) detector to receive a primary oscillator signal and to produce an AM detector signal, the primary oscillator signal including a first PM noise; and a control circuit to receive the AM detector signal, to produce a control signal, and to communicate the control signal to a phase shifter, wherein the phase shifter receives the primary oscillator signal and control signal, and the oscillator produces a secondary oscillator signal that includes a second PM noise that is less than the first PM noise, and further including; a PM detector and power splitter receives the primary oscillator signal, splits a power of the primary oscillator signal, and communicates the primary oscillator signal to the AM detector and PM detector.

# PHASE MODULATION NOISE REDUCER

## STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

This invention was made with United States government support from the National Institute of Standards and Technology. The government has certain rights in the invention.

## BRIEF DESCRIPTION

Disclosed is a phase modulation (PM) noise reducer to reduce phase modulation noise of an oscillator, the PM noise reducer comprising: an amplitude modulation (AM) detector to receive a primary oscillator signal and to produce an AM detector signal based on the primary oscillator signal, the primary oscillator signal comprising a first phase modulation (PM) noise; a control circuit in electrical communication with the AM detector to receive the AM detector signal and to produce a control signal; a phase shifter in electrical communication with the control circuit to receive the primary oscillator signal and the control signal and to produce a secondary oscillator signal based on the primary oscillator signal and the control signal, the secondary oscillator signal comprising a second PM noise, wherein the second PM noise is less than the first PM noise.

Further disclosed is a phase modulation (PM) noise reducer to reduce phase modulation noise of an oscillator, the reducer comprising: an amplitude modulation (AM) detector to receive a primary oscillator signal from an oscillator and to produce an AM detector signal based on the primary oscillator signal, the primary oscillator signal comprising a first phase modulation (PM) noise; and a control circuit in electrical communication with the AM detector to receive the AM detector signal, to produce a control signal, and to communicate the control signal to a phase shifter disposed in the oscillator, wherein the phase shifter is configured to receive the primary oscillator signal and the control signal, and the oscillator is configured to produce a secondary oscillator signal in response to the phase shifter receiving the control signal from the control circuit, the secondary oscillator signal comprising a second PM noise that is less than the first PM noise.

Disclosed also is a process for reducing a phase modulation noise of an oscillator, the process comprising: receiving, by an amplitude modulation (AM) detector, a primary oscillator signal from an oscillator, the primary oscillator signal comprising a first modulation (PM) noise; producing, by the AM detector, an AM detector signal based on the primary oscillator signal; receiving, by a phase modulation (PM) detector, the primary oscillator signal from the oscillator; producing, by the PM detector, a PM detector signal based on the primary oscillator signal; receiving, by a control circuit, the AM detector signal from the AM detector and the PM detector signal from the PM detector; producing, by the control circuit: an AM detector transfer function; a PM detector transfer function; and a control signal from the AM detector transfer function and the PM detector transfer function; receiving, by a phase shifter, the primary oscillator signal and the control signal; and producing, by the phase shifter, a secondary oscillator signal comprising a second PM noise that is less than the first PM noise to reduce the PM noise of the oscillator.

## BRIEF DESCRIPTION OF THE DRAWINGS

The following descriptions should not be considered limiting in any way. With reference to the accompanying drawings, like elements are numbered alike.

FIG. 1 shows an embodiment of a phase modulation (PM) noise reducer;

FIG. 2 shows an embodiment of a PM noise reducer;

FIG. 3 shows an embodiment of a PM noise reducer;

FIG. 4 shows an embodiment of a PM noise reducer;

FIG. 5 shows an embodiment of a PM detector;

FIG. 6 shows an embodiment of an amplitude modulation detector and control circuit;

FIG. 7 shows an embodiment of an amplitude modulation detector and control circuit;

FIG. 8 shows an embodiment of an amplitude modulation detector and control circuit;

FIG. 9 shows an embodiment of an amplitude modulation detector and control circuit;

FIG. 10 shows a flowchart of an embodiment for reducing a phase modulation noise;

FIG. 11 shows a graph of double side band noise versus offset frequency;

FIG. 12 shows a graph of double side band noise versus offset frequency;

FIG. 13 shows a graph of double side band PM noise versus offset frequency;

FIG. 14 shows a graph of double side band noise versus vibration frequency; and

FIG. 15 shows a graph of double side band noise versus vibration frequency.

## DETAILED DESCRIPTION

A detailed description of one or more embodiments is presented herein by way of exemplification and not limitation.

It has been discovered that a phase modulation (PM) noise reducer described herein provides reduction of PM noise of an oscillator from correlation between amplitude modulated (AM) noise and PM noise produced by the oscillator. From the PM noise and AM noise, a control signal having substantially equal magnitude and frequency response with an opposite phase as the PM noise is used to reduce PM noise of the oscillator in a feedforward error correction process. Advantageously, the PM noise reducer achieves PM noise reduction of the oscillator when the oscillator is subjected to vibration.

In an embodiment, as shown in FIG. 1, phase modulation (PM) noise reducer 2 is configured to reduce phase modulation noise of oscillator 6. PM noise reducer 2 includes amplitude modulation (AM) detector 4 to receive a primary oscillator signal from oscillator 6 and to produce an AM detector signal based on the primary oscillator signal. The primary oscillator signal can include a first PM noise. PM noise reducer 2 also includes control circuit 12 in electrical communication with AM detector 4 to receive the AM detector signal and to produce a control signal. Phase shifter 14 is in electrical communication with control circuit 12 and is configured to receive the primary oscillator signal from splitter 8 and the control signal (at phase shifter control port 20) and to produce a secondary oscillator signal based on the primary oscillator signal and the control signal. Here, the secondary oscillator signal includes a second PM noise that is less than the first PM noise. It should be appreciated that phase shifter 14 is arranged external to oscillator 6. Phase shifter 14 can be, e.g., a voltage variable phase shifter.

Power splitter 8 is interposed between oscillator 6 and AM detector 4 and is in electrical communication with AM detector 4 and phase shifter 14. Power splitter 8 is configured to receive the primary oscillator signal prior to AM detector 4 and phase shifter 14, to split a power of the primary oscillator signal along; and to communicate the primary oscillator sig-

nal to AM detector **4** along first line **10** and to phase shifter **14** along second line **16**. PM noise reducer **2** also optionally includes PM detector **18** to receive the primary oscillator signal, to produce a PM detector signal in response to receiving the primary oscillator signal, and to communicate the PM detector signal to control circuit **12**. In this configuration, control circuit **12** produces the control signal in response to receiving the AM detector signal and the PM detector signal.

According to an embodiment, as shown in FIG. **2**, AM detector **4** includes diode **22** in electrical communication with power splitter **8** to receive the primary oscillator signal from power splitter **8** and also includes capacitor **24** in electrical communication with diode **22** to provide the AM detector signal to control circuit **12**. Additionally, AM detector **4** further includes amplifier **26** in electrical communication with capacitor **24** and interposed capacitor **24** and control circuit **12** to amplify the AM detector signal.

In an embodiment, with reference to FIG. **3** and FIG. **4**, PM noise reducer **2** is configured to reduce phase modulation noise of oscillator **28**. Here, PM noise reducer **2** includes AM detector **4** to receive a primary oscillator signal from oscillator **28** and to produce an AM detector signal based on the primary oscillator signal, wherein the primary oscillator signal includes a first PM noise. PM noise reducer **2** also includes control circuit **12** in electrical communication with AM detector **4** to receive the AM detector signal, to produce a control signal, and to communicate the control signal to phase shifter control port **20** of phase shifter **14** that is disposed in oscillator **28**. Phase shifter **14** is configured to receive the primary oscillator signal and the control signal, and oscillator **28** is configured to produce a secondary oscillator signal in response to phase shifter **20** receiving the control signal from control circuit **12**. It is contemplated that the secondary oscillator signal includes a second PM noise that is less than the first PM noise.

Additionally, PM noise reducer **2** includes PM detector **18** (optionally) and power splitter **38** in electrical communication with AM detector **4** and PM detector **18**. Power splitter **38** is configured to receive the primary oscillator signal from oscillator **28** prior to AM detector **4** and PM detector **18**, to split a power of the primary oscillator signal, and to communicate the primary oscillator signal to AM detector **4** along third line **40** and to PM detector **18** along fourth line **40**. PM detector **18** is configured to receive the primary oscillator signal from power splitter **38**, to produce a PM detector signal in response to receiving the primary oscillator signal, and to communicate the PM detector signal to control circuit **12**.

AM detector **4** can include diode **22** in electrical communication with power splitter **38** to receive the primary oscillator signal from power splitter **38** and capacitor **24** in electrical communication with diode **22** to provide the AM detector signal to control circuit **12**. AM detector **4** can further include amplifier **26** in electrical communication with capacitor **24** and interposed between capacitor **24** and control circuit to **12** amplify the AM detector signal. In this arrangement, control circuit **12** is configured to produce the control signal in response to receiving the AM detector signal and the PM detector signal and to communicate the control signal to phase shifter control port **20** of phase shifter **14** disposed in oscillator **28**.

With reference to FIG. **4**, in an embodiment, oscillator **28** having phase shifter **14** disposed therein also includes resonator **32** to produce the primary oscillator signal, amplifier **36** to receive the primary oscillator signal or secondary oscillator signal from phase shifter **14** via attenuator **34**, and splitter **8** to split the primary oscillator signal between first line **10** and

second line **16**, and attenuator **32** interposed between resonator **32** and splitter **8** to attenuate the primary oscillator signal.

With reference to FIG. **5**, PM detector **18** is in electrical communication with oscillator (e.g., oscillator **6** or oscillator **28**) to receive primary oscillator signal **19** and produce PM detector signal **21**. According to an embodiment, PM detector **18** includes local oscillator **46** to produce a local oscillator signal, demodulator **44** configured to receive the primary oscillator signal and the local oscillator signal and to produce a demodulator signal, and sampler **48** to receive the demodulator signal from demodulator **44** and to produce PM detector signal **21**, which is communicated to control circuit **12**. Demodulator **44** can be an I-Q demodulator that produces an in-phase (I) signal that is communicated to amplifier **50** prior to communication to sampler **48** and also produces a quadrature (Q) signal that is communicated to amplifier **52** prior to communication to sampler **48**. The in-phase signal and quadrature signal are based on primary oscillator signal **19** and have a phase difference of 90°. In a certain embodiment, sampler **48** is configured to acquire a discreet sample from the in-phase signal and a discreet sample from quadrature signal from demodulator **44**. It is contemplated that PM detector **18** can be present in PM noise reducer **2** when PM noise is determined for producing the AM detector transfer function $H_{AM}(f)$ or phase shifter transfer function $H_{PS}(f)$. Thereafter, PM detector **18** can be present but not activated or absent from PM noise reducer **2**.

It is contemplated that control circuit **12** can be an analog circuit configured to receive an analog signal or a digital signal Control circuit **12** also can produce the control signal as an analog signal or digital signal. Further, control circuit **12** can process an electrical signal using analog signal processing, digital signal processing, or a combination thereof. In a certain embodiment, as show in FIG. **6**, control circuit **12** performs digital signal processing and is in electrical communication with AM detector **4**, amplifier **26**, phase modulation detector **18**, and phase shifter **14** (not shown) disposed external to oscillator **6** (not shown). Here, control circuit **12** includes analog-to-digital converter **54** to receive the AM detector signal and PM detector signal, integrator-digital filter **56** to receive a digital signal from converter **54** and to produce and communicate the control signal to digital-to-analog converter **58**. Converter **58** is configured to communicate the control signal to phase shifter **14**. In some embodiments, control circuit **12** includes a field programmable gate array that can include filter **56**.

According to an embodiment, as show in FIG. **7**, control circuit **12** performs analog signal processing and is in electrical communication with AM detector **4**, amplifier **26**, phase modulation detector **18**, and phase shifter **14** (not shown) disposed external to oscillator **6** (not shown). Here, control circuit **12** includes integrator **60** to receive the AM detector signal and PM detector signal, analog filter **62** to receive an analog signal from integrator **60** and to produce and communicate the control signal to phase shifter **14**.

In a certain embodiment, as show in FIG. **8**, control circuit **12** performs digital signal processing and is in electrical communication with AM detector **4**, amplifier **26**, phase modulation detector **18**, and phase shifter **14** (not shown) disposed in oscillator **28** (not shown). Here, control circuit **12** includes analog-to-digital converter **54** to receive the AM detector signal and PM detector signal, digital filter **64** to receive a digital signal from converter **54** and to produce and communicate the control signal to digital-to-analog converter **58**. Converter **58** is configured to communicate the control signal

to phase shifter **14** in oscillator **28**. In some embodiments, control circuit **12** includes a field programmable gate array that can include filter **64**.

According to an embodiment, as show in FIG. **9**, control circuit **12** performs analog signal processing and is in electrical communication with AM detector **4**, amplifier **26**, phase modulation detector **18**, and phase shifter **14** (not shown) disposed in oscillator **28** (not shown). Here, control circuit **12** includes analog filter **62** to receive the AM detector signal and PM detector signal and to produce and communicate the control signal to phase shifter **14**.

In a certain embodiment, control circuit **12** includes analog-to-digital converter **54** to receive the AM detector signal and the PM detector signal, a field programmable gate array in electrical communication with analog-to-digital converter **54** and including an integrator and a digital filter, and digital-to-analog converter **58** in electrical communication with the field programmable gate array to communicate the control signal to phase shifter **14**. According to an embodiment, control circuit **12** is configured to produce an AM detector transfer function that is a result of determination a ratio of the AM detector signal to the PM detector signal, and to produce a phase shifter transfer function, and to produce the control signal that includes a conjugate filter that is a result of a ratio of the AM detector transfer function and the phase shifter transfer function.

In a particular embodiment, control circuit **12** includes integrator **60** to receive the AM detector signal and the PM detector signal, analog filter **62** in electrical communication with integrator **60** to communicate the control signal to phase shifter **14**. Control circuit **12** is configured to produce an AM detector transfer function that is a result of a ratio of the AM detector signal to the PM detector signal, to produce a phase shifter transfer function, and to produce the control signal that includes a conjugate filter that is a result of a ratio of the AM detector transfer function and the phase shifter transfer function.

In an embodiment, a process for making PM noise reducer **2** includes connecting splitter **8** to oscillator **6**, connecting AM detector **4** and phase shifter **14** to splitter **8**, optionally connecting phase shifter **14** to phase modulation detector **18**, and connecting control circuit **12** to AM detector **4**, phase modulation detector **18** (optionally), and phase shifter control port **20** of phase shifter **14**.

According to an embodiment, a process for making PM noise reducer **2** includes connecting splitter **38** to oscillator **28**, optionally connecting AM detector **4** and PM detector **18** to splitter **38**, connecting control circuit **12** to phase modulation detector **18** (optionally) and AM detector **4** as inputs, and connecting control circuit **12** to phase shifter control port **20** of phase shifter **14** as an output. Here, it is contemplated that PM detector **18** can be present in PM noise reducer **2** when PM noise is determined for producing the AM detector transfer function $H_{AM}(f)$ or phase shifter transfer function $H_{PS}(f)$. Thereafter, PM detector **18** can be present but not activated or absent from PM noise reducer **2**.

According to an embodiment, with reference to FIG. **10** a process for reducing a phase modulation noise of an oscillator includes receiving, by AM detector **4**, a primary oscillator signal (step **66**) from an oscillator (e.g., oscillator **6** or oscillator **28**), the primary oscillator signal including a first PM noise; producing, by AM detector **4**, an AM detector signal (step **68**) based on the primary oscillator signal; receiving, by PM detector **18**, the primary oscillator signal from the oscillator; and producing, by PM detector **18**, a PM detector signal (step **70**) based on the primary oscillator signal; receiving, by control circuit **12**, the AM detector signal from AM detector **4**

and the PM detector signal from PM detector **18**. The process also includes producing, by control circuit **12**: an AM detector transfer function, a PM detector transfer function, and a control signal (step **72**) from the AM detector transfer function and the PM detector transfer function; receiving, by phase shifter **14**, the primary oscillator signal and the control signal; and producing, by phase shifter **14**, a secondary oscillator signal (step **74**) that includes a second PM noise that is less than the first PM noise to reduce the PM noise of the oscillator.

In a process for determining the control signal, the process includes measuring a double-sideband (DSB) PM noise ($S_\phi$), AM noise ($S_\alpha$), and cross-power spectral density (CPSD) ($S_{\phi\alpha}$) between the PM noise and the AM noise. The process also include determining a slope and correlation between the PM noise and the AM noise. Here, correlation between the PM noise and AM noise is correlation coefficient ρ provided in formula 1.

$$\rho = \frac{S_{\varphi\alpha}}{\sqrt{S_\varphi S_\alpha}} \tag{1}$$

where $\sqrt{S_\phi S_\alpha}$ is a geometric mean of PM noise and AM noise, and ρ has a value from 0 to 1, wherein ρ=1 for 100% correlation between the PM noise and AM noise. Further, control circuit **12** produces the control signal by using the AM noise that is of a substantially same magnitude, substantially same noise slope, and opposite phase as the PM noise. The control signal produced therefrom is used to produce the secondary oscillator signal having the second PM noise that is less than the first PM noise of the oscillator (e.g., oscillator **6** or oscillator **28**), wherein the control signal is received by phase shifter **14** in a feed-forward manner to reduce the first PM noise to the second PM noise. To produce the control signal, control circuit **12** produces AM detector transfer function $H_{AM}(f)$ and phase shifter transfer function $H_{PS}(f)$ to determine conjugate filter $H_C(f)$ that is a result of a ratio of AM detector transfer function $H_{AM}(f)$ and phase shifter transfer function $H_{PS}(f)$.

AM detector transfer function $H_{AM}(f)$ is determined from a ratio of the AM noise received by control circuit **12** from AM detector **4** to the PM noise of the oscillator (e.g., oscillator **6** or oscillator **28**). Phase shifter transfer function $H_{PS}(f)$ is determined from a ratio of control port **20** of phase shifter **14** to the PM noise of the oscillator (e.g., oscillator **6** or oscillator **28**). Accordingly, conjugate filter $H_C(f)$ of the control signal is provided by formula (2).

$$H_C = -\frac{H_{AM}(f)}{H_{PS}(f)} \tag{1}$$

The AM signal is filtered with the conjugate filter $H_C(f)$ and communicated as the control signal to the control port of phase shifter **14**.

PM noise reducer **2** has numerous benefits and advantages. PM noise reducer **2** reduces PM noise of an oscillator from determination of the AM noise of the primary oscillator signal instead of referencing the PM noise of the oscillator to a secondary oscillator that is well and more stable than the oscillator. Further, the primary oscillator signal can have a frequency from 10 kilohertz (kHz) to 3000 terahertz (THz), specifically from 100 kHz to 1000 gigahertz (GHz), and more specifically from 1 megahertz (MHz) to 200 GHz The pri-

mary oscillator signal can operate with a carrier power from 1 nanowatt (nW) to 1 megawatts (MW), specifically from 1 microwatts (uW) to 1 kilowatts (kW), and more specifically from 1 milliwatt (mW) to 10 watts (MW). The primary oscillator signal can have a duty cycle from 5% to 95%, based on a total on-time of a waveform of the primary oscillator signal. The waveform of the primary oscillator signal can have a shape including square wave, triangular, sawtooth, sinusoidal, asymmetric, and the like. The PM noise of the primary oscillator signal can be from $-200$ dBrad$^2$/Hz to 100 dBrad$^2$/Hz, specifically from $-180$ dBrad$^2$/Hz to 40 dBrad$^2$/Hz units, and more specifically from $-160$ dBrad$^2$/Hz to $-50$ dBrad$^2$/Hz. The AM noise of the primary oscillator signal can be from $-200$ dB/Hz to 0 dB/Hz, specifically from $-180$ dB/Hz to $-120$ dB/Hz units, and more specifically from $-160$ dB/Hz to $-100$ dB/Hz.

Further, the secondary oscillator signal can have a frequency from 10 kHz to 3000 THz, specifically from 100 kHz to 1000 GHz, and more specifically from 1 MHz to 200 GHz. The secondary oscillator signal can operate with a carrier power from 1 nW to 1 MW, specifically from 1 microwatt ($\mu$W) to 1 kW, and more specifically from 1 mW to 10 MW. The secondary oscillator signal can have a duty cycle from 5% to 95%, based on a total on-time of a waveform of the secondary oscillator signal. The waveform of the secondary oscillator signal can have a shape including square wave, triangular, sawtooth, sinusoidal, asymmetric, and the like. The PM noise of the secondary oscillator signal can be from $-200$ dBrad$^2$/Hz to 100 dBrad$^2$/Hz, specifically from $-180$ dBrad$^2$/Hz to 40 dBrad$^2$/Hz units, and more specifically from $-160$ dBrad$^2$/Hz to $-50$ dBrad$^2$/Hz. The AM noise of the primary oscillator signal can be from $-200$ dB/Hz to 0 dB/Hz, specifically from $-180$ dB/Hz to $-120$ dB/Hz units, and more specifically from $-160$ dB/Hz to $-100$ dB/Hz.

In comparing the primary oscillator signal provided by the oscillator (e.g., oscillator 6 or oscillator 28) to the secondary oscillator signal, an improvement of the PM noise of the oscillator is improved by greater than 30 decibels (dB), specifically greater than 20 dB, and more specifically greater than 10 dB for a frequency offset with strong correlation between the PM noise and the AM noise and the primary oscillator signal.

Accordingly, rather than correcting the PM noise in the primary oscillator signal from the oscillator by measuring the PM noise in real time, measurement of AM noise is performed with a reference voltage, e.g., a diode and a capacitor in the AM detector rather than a reference oscillator for real-time PM noise determination. Advantageously the AM noise of the oscillator is measured with the AM detector and a control signal of equal magnitude, same frequency response but opposite phase as the PM noise is produced by the control circuit. This control signal is used to reduce the PM noise of the oscillator via the above-described feedforward error correction. Beneficially, PM noise reducer 2 can be used to reduce PM noise of an oscillator to produce the secondary oscillator signal

The articles and processes herein are illustrated further by the following Examples, which are non-limiting.

EXAMPLES

Example 1

PM Noise Correlation without PM Noise Reduction

An arbitrary waveform function generator (AWFG, commercially available from Rigol, model DG4160) was con-

nected to a commercial signal generator (commercially available from Agilent, model E8257D). Output from the signal generator was simultaneously FM modulated and AM modulated by the arbitrary waveform function generator to produce nearly 100% correlation. The AM noise spectrum and PM noise spectrum were acquired using an Analog Devices I/Q Demodulator (ADL5387) and a National Instruments dynamic signal analyzer (PXI4461). FIG. 11 shows a graph of double sideband (DSB) noise versus offset frequency for PM noise of the oscillator signal, AM noise, and correlation between the PM noise and the AM noise. A differential slope between the PM noise and the AM noise was $f^2$, and the correlation was nearly 100%.

Example 2

PM Noise Reducer and PM Noise Reduction

The signal generator and AWFG described in Example 1 were connected to a PM noise reducer. The PM noise reducer included a Mini-Circuits power splitter (ZFSC-2-1W), Herotek AM detector (DHM124AA), Stanford Research amplifier (SIM 911), mini-circuits phase shifter (PS, JSPHS-661), National Instruments ADC/DAC (NI 5791), and FPGA processor (NI PXI-7954 R), which were configured as shown in FIG. 2.

The signal generator was first operated by disabling the control signal to the PS external to the signal generator, and DSB noise as function of offset frequency was acquired. Similarly, the signal generator was operated by enabling the control signal that was generated by measuring two transfer functions $H_{PS}$ and $H_{AM}$, and DSB noise as function of offset frequency was acquired. The transfer functions as well as the AM noise spectrum and PM noise spectrum were acquired by the I/Q Demodulator and a signal analyzer. FIG. 12 shows a graph of double sideband (DSB) noise versus offset frequency for corrected and uncorrected PM noise from the oscillator. An improvement greater than 20 dB over two decades of offset frequencies was observed. Accordingly, when the oscillator exhibited strong correlation between PM and AM noise, the AM noise was used to compensate the PM noise.

Example 3

Quartz MEMS Oscillator

An oscillator at 635 MHz was constructed with a custom-built quartz-MEMS resonator and an amplifier (Mini-Circuits ERA-5), configured as shown in FIG. 4. The phase shifter (PS) was disposed inside the loop, and the input and output power of the resonator inside the loop was adjusted using variable attenuators (Hewlett Packard 8494A). The oscillator was connected to the PM noise reducer that included a power splitter (Mini-Circuits ZFSC-2-1W), AM detector (Herotek DHM124AA), amplifier (Stanford Research SIM 911), a phase shifter (Mini-Circuits JSPHS-661), ADC/DAC, (National Instruments NI 5791), and FPGA processors (National Instruments PXI-7954 R). The oscillator was operated by disabling the control signal to the PS, and DSB noise as function of offset frequency was acquired. In a separate experiment, the oscillator was operated by enabling the control signal that was generated by measuring two transfer functions $H_{PS}$ and $H_{AM}$, and DSB noise as function of offset frequency was acquired. FIG. 13 shows a graph of double sideband (DSB) noise versus offset frequency for corrected and uncorrected PM noise from the oscillator. An improve-

9

ment of 10 dB from 2 Hz to 100 Hz offset frequencies was observed. The oscillator exhibited less than 100% correlation between PM and AM noise, and the AM noise was used to compensate the PM noise.

Example 4

Vibration Testing

The oscillator and PM noise reducer described in Example 3 were connected and subjected to vibration testing. The oscillator was mounted on a vibration actuator (Lab Works ET-139) and tested under constant acceleration white noise from 20 Hz to 200 Hz such that an acceleration power spectral density was 0.005 $g^2$/Hz. The oscillator under vibration was operated by disabling the control signal to the PS, and DSB noise as function of offset frequency was acquired as shown in FIG. **14**. A differential slope between the PM noise and the AM noise was $f^2$, and the correlation was greater than 90%. This high level of vibration induced correlation was observed in other test oscillators that showed low levels of steady-state correlation. In another test, the oscillator was operated by enabling the control signal that was generated by measuring two transfer functions $H_{PS}$ and $H_{AM}$, and DSB noise as function of offset frequency was acquired. FIG. **15** shows a graph of double sideband (DSB) noise versus offset frequency for corrected and uncorrected PM noise from the oscillator. An improvement of 15 dB from 20 Hz to 200 Hz offset frequencies was observed. PM noise reducer reduced phase noise of the oscillator subjected to vibration and improved its vibration insensitivity.

While one or more embodiments have been shown and described, modifications and substitutions may be made thereto without departing from the spirit and scope of the invention. Accordingly, it is to be understood that the present invention has been described by way of illustrations and not limitation. Embodiments herein can be used independently or can be combined.

Reference throughout this specification to "one embodiment," "particular embodiment," "certain embodiment," "an embodiment," or the like means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment. Thus, appearances of these phrases (e.g., "in one embodiment" or "in an embodiment") throughout this specification are not necessarily all referring to the same embodiment, but may. Furthermore, particular features, structures, or characteristics may be combined in any suitable manner, as would be apparent to one of ordinary skill in the art from this disclosure, in one or more embodiments.

All ranges disclosed herein are inclusive of the endpoints, and the endpoints are independently combinable with each other. The ranges are continuous and thus contain every value and subset thereof in the range. Unless otherwise stated or contextually inapplicable, all percentages, when expressing a quantity, are weight percentages. The suffix "(s)" as used herein is intended to include both the singular and the plural of the term that it modifies, thereby including at least one of that term (e.g., the colorant(s) includes at least one colorants). "Optional" or "optionally" means that the subsequently described event or circumstance can or cannot occur, and that the description includes instances where the event occurs and instances where it does not. As used herein, "combination" is inclusive of blends, mixtures, alloys, reaction products, and the like.

As used herein, "a combination thereof" refers to a combination comprising at least one of the named constituents,

10

components, compounds, or elements, optionally together with one or more of the same class of constituents, components, compounds, or elements.

All references are incorporated herein by reference.

The use of the terms "a" and "an" and "the" and similar referents in the context of describing the invention (especially in the context of the following claims) are to be construed to cover both the singular and the plural, unless otherwise indicated herein or clearly contradicted by context. "Or" means "and/or." Further, the conjunction "or" is used to link objects of a list or alternatives and is not disjunctive; rather the elements can be used separately or can be combined together under appropriate circumstances. It should further be noted that the terms "first," "second," "primary," "secondary," and the like herein do not denote any order, quantity, or importance, but rather are used to distinguish one element from another. The modifier "about" used in connection with a quantity is inclusive of the stated value and has the meaning dictated by the context (e.g., it includes the degree of error associated with measurement of the particular quantity).

What is claimed is:

1. A phase modulation (PM) noise reducer to reduce phase modulation noise of an oscillator, the PM noise reducer comprising:
   an amplitude modulation (AM) detector to receive a primary oscillator signal from the oscillator and to produce an AM detector signal based on the primary oscillator signal, the primary oscillator signal comprising a first phase modulation (PM) noise;
   a control circuit in electrical communication with the AM detector to receive the AM detector signal, to produce a control signal, and to communicate the control signal to a phase shifter disposed in the oscillator;
   a phase modulation (PM) detector; and
   a power splitter in electrical communication with the AM detector and the PM detector, the power splitter being configured:
      to receive the primary oscillator signal prior to the AM detector and the PM detector;
      to split a power of the primary oscillator signal; and
      to communicate the primary oscillator signal to the AM detector and to the PM detector,
   wherein the phase shifter is configured to receive the primary oscillator signal and the control signal, and
   the oscillator is configured to produce a secondary oscillator signal in response to the phase shifter receiving the control signal from the control circuit, the secondary oscillator comprising a second PM noise that is less than the first PM noise.

2. The PM noise reducer of claim **1**, wherein the AM detector comprises:
   a diode in electrical communication with the power splitter to receive the primary oscillator signal from the power splitter; and
   a capacitor in electrical communication with the diode to provide the AM detector signal to the control circuit.

3. The PM noise reducer of claim **2**, wherein the AM detector further comprises an amplifier in electrical communication with the capacitor and interposed between the capacitor and the control circuit to amplify the AM detector signal.

4. The PM noise reducer of claim **3**, wherein the PM detector is configured to receive the primary oscillator signal from the power splitter, to produce a PM detector signal in response to receiving the primary oscillator signal, and to communicate the PM detector signal to the control circuit.

**5**. The PM noise reducer of claim **4**, wherein the PM detector comprises:

a local oscillator to produce a local oscillator signal;

a demodulator to receive the primary oscillator signal and the local oscillator signal and to produce a demodulator signal; and

a sampler to receive the demodulator signal from the demodulator and to produce the PM detector signal.

**6**. The PM noise reducer of claim **5**, wherein the control circuit comprises:

an analog-to-digital converter to receive the AM detector signal and the PM detector signal;

a field programmable gate array in electrical communication with the analog-to-digital converter comprising a digital filter; and

a digital to analog converter in electrical communication with the field programmable gate array to communicate the control signal to the phase shifter.

**7**. The PM noise reducer of claim **6**, wherein the control circuit is configured to:

produce an AM detector transfer function that is a result of a ratio of the AM detector signal to the PM detector signal;

produce a phase shifter transfer function; and

produce the control signal comprising a conjugate filter that is a result of a ratio of the AM detector transfer function and the phase shifter transfer function.

**8**. The PM noise reducer of claim **5**, wherein the control circuit comprises an analog filter to receive the AM detector signal and the PM detector signal and to communicate the control signal to the phase shifter.

**9**. The PM noise reducer of claim **8**, wherein the control circuit is configured to:

produce an AM detector transfer function that is a result of a ratio of the AM detector signal to the PM detector signal;

produce a phase shifter transfer function; and

produce the control signal comprising a conjugate filter that is a result of a ratio of the AM detector transfer function and the phase shifter transfer function.
